

# Simple Linear Regression: $R^2$

---

- Given no linear association:
  - We could simply use the sample mean to predict  $E(Y)$ . The variability using this simple prediction is given by SST (to be defined shortly).
  
- Given a linear association:
  - The use of  $X$  permits a potentially better prediction of  $Y$  by using  $E(Y|X)$ .
  - **Question:** What did we gain by using  $X$ ?

Let's examine this question with the following figure

# Decomposition of sum of squares

# Decomposition of sum of squares

It is always true that:  $y_i - \bar{y} = (y_i - \hat{y}_i) + (\hat{y}_i - \bar{y})$

It can be shown that:

$$\sum_{i=1}^n (y_i - \bar{y})^2 = \sum_{i=1}^n (y_i - \hat{y}_i)^2 + \sum_{i=1}^n (\hat{y}_i - \bar{y})^2$$
$$SST = SSE + SSR$$

**SST:** describes the total variation of the  $Y_i$ .

**SSE:** describes the variation of the  $Y_i$  around the regression line.

**SSR:** describes the structural variation; how much of the variation is due to the regression relationship.

This decomposition allows a characterization of the usefulness of the covariate  $X$  in predicting the response variable  $Y$ .

# Simple Linear Regression: $R^2$

- Given no linear association:
  - We could simply use the sample mean to predict  $E(Y)$ . The variability between the data and this simple prediction is given as  $SST$ .
- Given a linear association:
  - The use of  $X$  permits a potentially better prediction of  $Y$  by using  $E(Y|X)$ .
  - **Question:** What did we gain by using  $X$ ?
  - **Answer:** We can answer this by computing the proportion of the total variation that can be explained by the regression on  $X$

$$R^2 = \frac{SSR}{SST} = \frac{SST - SSE}{SST} = 1 - \frac{SSE}{SST}$$

- This  $R^2$  is, in fact, the correlation coefficient squared.

# Examples of $R^2$

$R^2 = 0.52$

$R^2 = 0.81$

$R^2 = 0.79$

$R^2 = 0.01$

Low values of  $R^2$  indicate that the model is not adequate. However, high values of  $R^2$  do not mean that the model is adequate!!

# Cholesterol Example:

Scientific Question: Can we predict cholesterol based on age?

```
> fit = lm(chol ~ age)
> summary(fit)

Call:
lm(formula = chol ~ age)

Residuals:
    Min       1Q   Median       3Q      Max
-60.45306 -14.64250  -0.02191  14.65925  58.99527

Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept) 166.90168    4.26488   39.134 < 2e-16 ***
age          0.31033    0.07524    4.125 4.52e-05 ***
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 21.69 on 398 degrees of freedom
Multiple R-squared: 0.04099, Adjusted R-squared: 0.03858
F-statistic: 17.01 on 1 and 398 DF, p-value: 4.522e-05
```

```
> confint(fit)

                2.5 %       97.5 %
(Intercept) 158.5171656 175.2861949
age          0.1624211   0.4582481
```

## Cholesterol Example:

Scientific Question: Can we predict cholesterol based on age?

---

- $R^2=0.04$
- What does  $R^2$  tell us about our model for cholesterol?

## Cholesterol Example:

Scientific Question: Can we predict cholesterol based on age?

---

- $R^2=0.04$
- What does  $R^2$  tell us about our model for cholesterol?
- **Answer:** 4% of the variability in cholesterol is explained by age. Although mean cholesterol increases with age, there is much more variability in cholesterol than age alone can explain

# Cholesterol Example:

Scientific Question: Can we predict cholesterol based on age?

- Decomposition of Sum of Squares and the F-statistic

```
> anova(fit)
Analysis of Variance Table

Response: chol
```

	Df	Sum Sq	Mean Sq	F value	Pr(>F)	
<b>SSR</b> =age	1	8002	8001.7	17.013	4.522e-05	***
<b>SSE</b> =Residuals	398	187187	470.3			

---  
Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Degrees of freedom  
Decomposition of the Sum of Squares  
Mean Squares: SS/df  
F-statistic: MSR/MSE

In simple linear regression:

$$F\text{-statistic} = (t\text{-statistic for slope})^2$$

Hypothesis being tested:  $H_0: \beta_1=0$ ,  $H_1: \beta_1 \neq 0$ .

# Simple Linear Regression: Assumptions

---

1.  $E[Y|x]$  is related linearly to  $x$
2.  $Y$ 's are independent of each other
3. Distribution of  $[Y|x]$  is normal
4.  $\text{Var}[Y|x]$  does not depend on  $x$

<p><b>L</b>inearity</p> <p><b>I</b>ndependence</p> <p><b>N</b>ormality</p> <p><b>E</b>qual variance</p>
---

Can we assess if these assumptions are valid?

# Model Checking: Residuals

---

- **(Raw or unstandardized) Residual:** difference ( $r_i$ ) between the observed response and the predicted response, that is,

$$\begin{aligned}r_i &= y_i - \hat{y}_i \\ &= y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i)\end{aligned}$$

The residual captures the component of the measurement  $y_i$  that cannot be “explained” by  $x_i$ .

# Model Checking: Residuals

---

- Residuals can be used to
  - Identify poorly fit data points
  - Identify unequal variance (heteroscedasticity)
  - Identify nonlinear relationships
  - Identify additional variables
  - Examine normality assumption

# Model Checking: Residuals

---

<b>L</b> inearity	Plot residual vs $X$ or vs $\hat{Y}$ Q: Is there any structure?
<b>I</b> ndependence	Q: Any scientific concerns?
<b>N</b> ormality	Residual histogram or qq-plot Q: Symmetric? Normal?
<b>E</b> qual variance	Plot residual vs $X$ Q: Is there any structure?

# Model Checking: Residuals

- If the linear model is appropriate we should see an **unstructured horizontal band of points centered at zero** as seen in the figure below

# Model Checking: Residuals

The model does not provide a good fit in these cases!

Violations of the model assumptions? How?

# Linearity

---

- The linearity assumption is important: interpretation of the slope estimate depends on the assumption of the same rate of change in  $E(Y|X)$  over the range of  $X$
- Preliminary  $Y$ - $X$  scatter plots and residual plots can help identify non-linearity
- If linearity cannot be assumed, consider alternatives such as polynomials, fractional polynomials, splines or categorizing  $X$

# Independence

---

- The independence assumption is also important: whether observations are independent will be known from the study design
- There are statistical approaches to accommodate dependence, e.g. dependence that arises from cluster designs

# Normality

---

- The Normality assumption can be visually assessed by a histogram of the residuals or a normal QQ-plot of the residuals
- A QQ-plot is a graphical technique that allows us to assess whether a data set follows a given distribution (such as the Normal distribution)
  - The data are plotted against a given theoretical distribution
    - Points should approximately fall in a straight line
    - Departures from the straight line indicate departures from the specified distribution.
- However, for moderate to large samples, the Normality assumption can be relaxed

See, e.g., Lumley T et al. The importance of the normality assumption in large public health data sets. *Annu Rev Public Health* 2002; 23: 151-169.

## Equal variance

---

- Sometimes variance of  $Y$  is not constant across the range of  $X$  (heteroscedasticity)
- Little effect on point estimates but variance estimates may be incorrect
- This may affect confidence intervals and p-values
- To account for heteroscedasticity we can
  - Use robust standard errors
  - Transform the data
  - Fit a model that does not assume constant variance (GLM)

## Robust standard errors

---

- Robust standard errors correctly estimate variability of parameter estimates even under non-constant variance
  - These standard errors use empirical estimates of the variance in  $y$  at each  $x$  value rather than assuming this variance is the same for all  $x$  values
- Regression point estimates will be unchanged
- Robust or empirical standard errors will give correct confidence intervals and p-values

# Cholesterol-Age example: Residuals

Plot of residuals versus fitted values

Structure?

Heteroscedasticity?

**R COMMAND:**

```
plot(fit$fitted, fit$residuals)
```

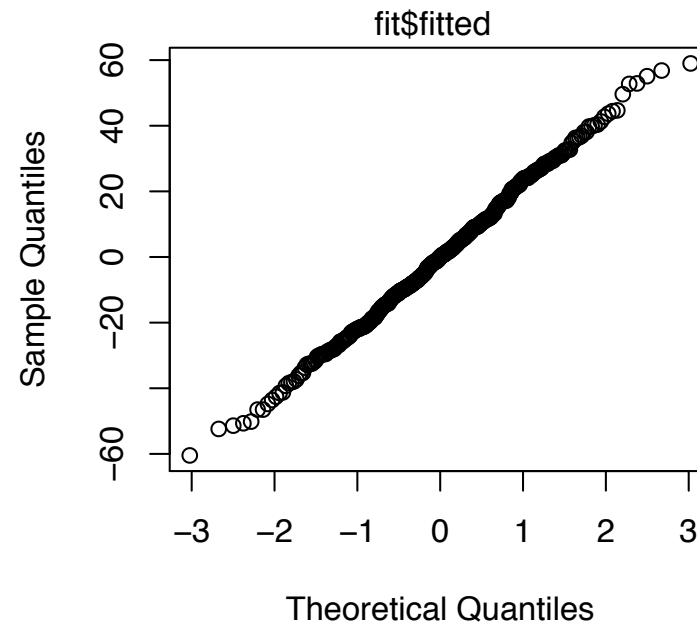

Plot of residuals versus quantiles of a normal distribution (for  $n > 30$ )

Normality?

**R COMMAND:**

```
qqnorm(fit$residuals)
```

## Another example

- Linear regression for association between age and triglycerides

```
> fit.tg=lm(TG~age)
```

# Robust standard errors

- Residual analysis suggests mean-variance relationship
- Use robust standard errors to get correct variance estimates

# Cholesterol example: Robust standard errors

## ■ Linear regression results:

```
> summary(fit.tg)

Call:
lm(formula = TG ~ age)

Coefficients:

```

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	-53.3059	11.1339	-4.788	2.38e-06 ***
age	4.2090	0.1964	21.429	< 2e-16 ***

Point estimates are unchanged

## ■ Results incorporating robust SEs:

```
> fit.tg.robust = coefTest(fit.tg, vcov = sandwich)
> fit.tg.robust

t test of coefficients:

```

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	-53.30593	8.73874	-6.100	2.515e-09 ***
age	4.20896	0.18134	23.211	< 2.2e-16 ***

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

# Cholesterol example: Robust standard errors

## Linear regression results:

```
> summary(fit.tg)
```

```
Call:
```

```
lm(formula = TG ~ age)
```

```
Coefficients:
```

	Estimate	Std. Error	t value	Pr(> t )	
(Intercept)	-53.3059	11.1339	-4.788	2.38e-06	***
age	4.2090	0.1964	21.429	< 2e-16	***

Standard errors  
are corrected

## Results incorporating robust SEs:

```
> fit.tg.robust = coeftest(fit.tg, vcov = sandwich)
```

```
> fit.tg.robust
```

```
t test of coefficients:
```

	Estimate	Std. Error	t value	Pr(> t )	
(Intercept)	-53.30593	8.73874	-6.100	2.515e-09	***
age	4.20896	0.18134	23.211	< 2.2e-16	***

```
---
```

```
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

# Transformations

---

- Some reasons for using data transformations
  - Content area knowledge suggests nonlinearity
  - Original data suggest nonlinearity
  - Equal variance assumption violated
  - Normality assumption violated
- Transformations may be applied to the response, predictor or both
  - Be careful with the interpretation of the results
- Rarely do we know which transformation of the predictor provides best “linear” fit – best to choose transformation on scientific grounds
  - As always, there is a danger in using the data to estimate the best transformation to use
    - If there is no association of any kind between the response and the predictor, a “linear” fit (with a zero slope) is the correct one
    - Trying to detect a transformation is thus an informal test for an association
      - Multiple testing procedures inflate the Type I error

## Model Checking: Outliers vs Influential observations

---

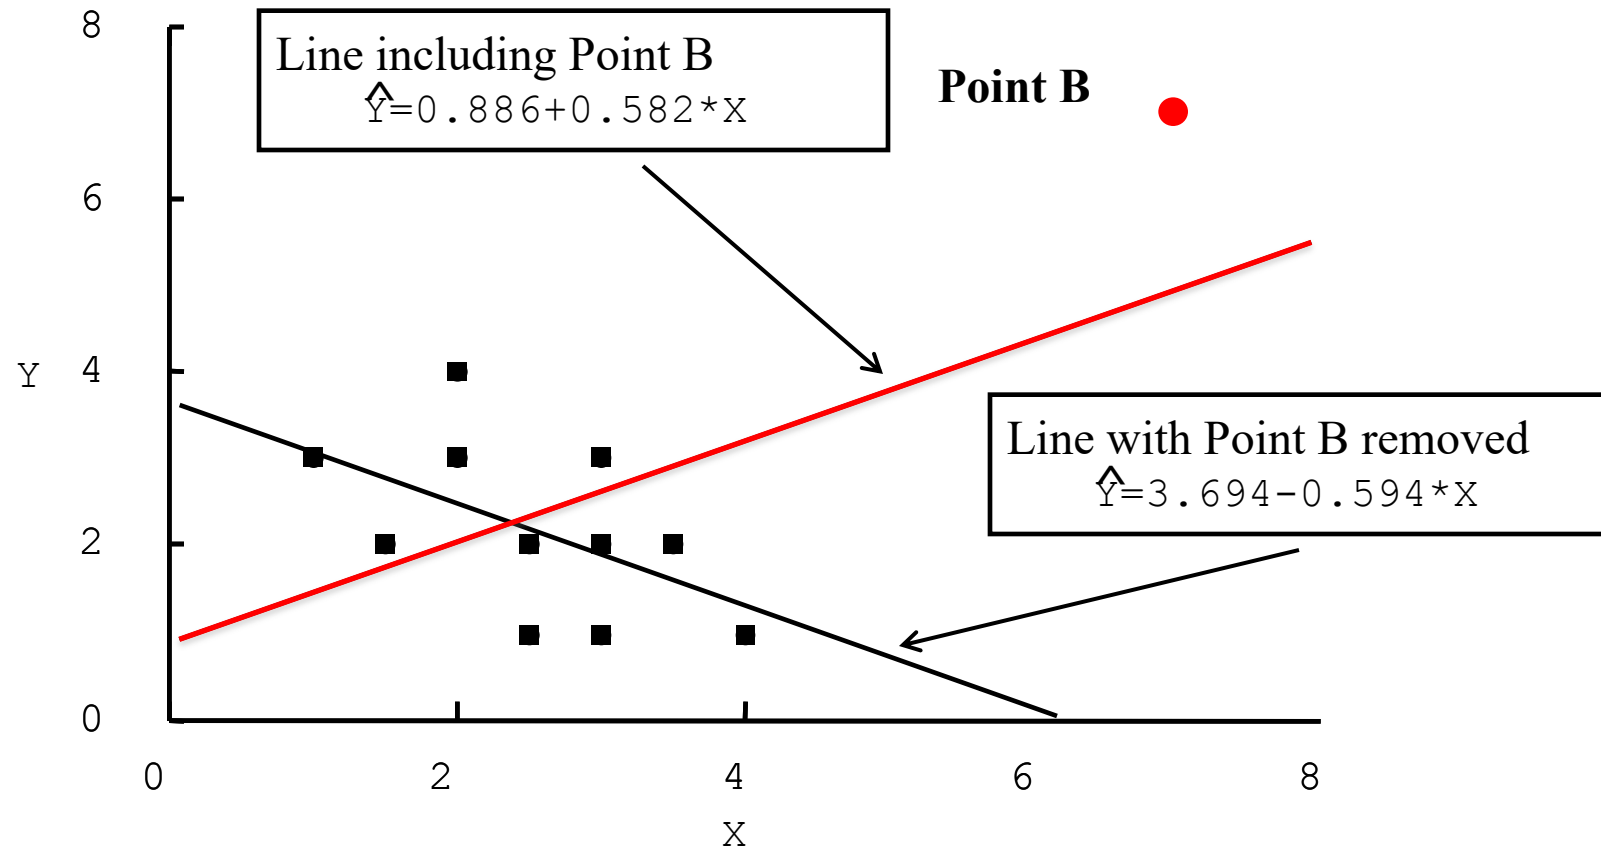

- **Outlier:** an observation with a residual that is unusually large (positive or negative) as compared to the other residuals.
- **Influential point:** an observation that has a notable influence in determining the regression equation.
  - Removing such a point would markedly change the position of the regression line.
  - Observations that are somewhat extreme for the value of  $x$  can be influential.

# Outlier vs Influential observations

Point A is an outlier, but is not influential.

# Outlier vs Influential observations

*Point B is influential, but not an outlier.*

# Cholesterol-Age Example: Residuals

No extreme outliers

# Model Checking: Deletion diagnostics

---

$$\Delta\beta_{(i)} = \hat{\beta} - \hat{\beta}_{(-i)} \quad : \text{Delta-beta}$$

$$\frac{\Delta\beta_{(i)}}{se(\hat{\beta})} \quad : \text{Standardized Delta-beta}$$

Delta-beta : tells how much the regression coefficient changed by excluding the  $i^{\text{th}}$  observation

Standardized delta-beta : approximates how much the t-statistic for a coefficient changed by excluding the  $i^{\text{th}}$  observation

# Cholesterol-Age Example: Deletion diagnostics

```
> dfb = dfbeta(fit)
> index=order(abs(dfb[,2]),decreasing=T)
> cbind(dfb[index[1:15],],age[index[1:15]])
```

	(Intercept)	age	
114	-0.9893663	0.015268514	34
166	-0.6827966	0.014888475	78
255	-0.6190643	0.013902713	75
186	-0.8544144	0.013279531	33
113	0.5376293	-0.011943495	76
325	-0.7517511	0.011308451	37
365	0.7676508	-0.011297278	39
257	-0.7374003	0.011092575	37
290	-0.7024787	0.010757541	35
144	0.7120264	-0.010710881	37
197	-0.6784150	0.010469720	34
296	-0.6499386	0.010101515	33
231	-0.6293174	0.009712016	34
7	0.4403297	-0.009524470	79
252	-0.5981020	0.009412761	31

No evidence of influential points. The largest (in absolute value) delta beta is 0.015 compared to the estimate of 0.31 for the regression coefficient.

# Model Checking

---

- What to do if you find an outlier and/or influential observation:
  - Check it for accuracy
  - Decide (based on scientific judgment) whether it is best to keep it or omit it
    - If you think it is representative, and likely would have appeared in a larger sample, keep it
    - If you think it is very unusual and unlikely to occur again in a larger sample, omit it
    - Report its existence [whether or not it is omitted]

# Simple Linear Regression: Impact of Violations of Model Assumptions

	Non Linearity	Non Normality	Unequal Variances	Dependence
Estimates	Problematic	Little impact for most departures. Extreme outliers can be a problem.	Little impact	Mostly little impact
Tests/CIs	Problematic	Little impact for most departures. CIs for correlation are sensitive.	Variance estimates may be wrong, but the impact is usually not dramatic	Variance estimates may be wrong
Correction	Choose a nonlinear approach (possible within the linear regression framework)	Mostly no correction needed. Delete outliers (if warranted) or use robust regression	Use robust standard errors	Regression for dependent data

# Exercise

---

- Work on **Exercises 4-6**
  - Try each exercise on your own
  - Make note of any questions or difficulties you have
  - At **1:15PM PT** we will meet as a group to go over the solutions and discuss your questions
